Lecture 15

18-640 Foundations of Computer Architecture

Lecture 15: “Multicore Parallel Programming”

- A. Introduction to Parallel Software
- B. Programming Models
- C. Major Abstractions
 - Processes & threads
 - Communication
 - Synchronization
- D. Shared Memory
- E. Message Passing

Carnegie Mellon University ²

10/28/2014 (© J.P. Shen)

Lecture 15

A. Introduction to Parallel Software

- Why is Parallel Programming so hard?
 - Conscious mind is inherently sequential
 - (sub-conscious mind is extremely parallel)
- Identifying parallelism in the problem
- Expressing parallelism to the hardware
- Effectively utilizing parallel hardware
 - Balancing work
 - Coordinating work
- Debugging parallel algorithms

Finding Parallelism

1. Functional parallelism
 - Car: {engine, brakes, entertain, nav, ...}
 - Game: {physics, logic, UI, render, ...}
 - Signal processing: {transform, filter, scaling, ...}
2. Automatic extraction
 - Decompose serial programs
3. Data parallelism
 - Vector, matrix, DB table, pixels, ...
4. Request parallelism
 - Web, shared database, telephony, ...

1. Functional Parallelism

1. Functional parallelism

- Car: {engine, brakes, entertain, nav, ...}
- Game: {physics, logic, UI, render, ...}
- Signal processing: {transform, filter, scaling, ...}
- Relatively easy to identify and utilize
- Provides small-scale parallelism
 - 3x-10x
- Balancing stages/functions is difficult

2. Automatic Extraction

2. Automatic extraction

- Decompose serial programs
- Works well for certain application types
 - Regular control flow and memory accesses
- Difficult to guarantee correctness in all cases
 - Ambiguous memory dependences
 - Requires speculation, support for recovery
- Degree of parallelism
 - Large (1000x) for *easy* cases
 - Small (3x-10x) for *difficult* cases

3. Data Parallelism

3. Data parallelism

- Vector, matrix, DB table, pixels, ...
- Large data => significant parallelism
- Many ways to express parallelism
 - Vector/SIMD
 - Threads, processes, shared memory
 - Message-passing
- Challenges:
 - Balancing & coordinating work
 - Communication vs. computation at scale

4. Request Parallelism

Web Browsing Users

- Multiple users => significant parallelism
- Challenges
 - Synchronization, communication, balancing work

Balancing Work

- Amdahl's parallel phase f : all processors busy
- If not perfectly balanced
 - $(1-f)$ term grows (f not fully parallel)
 - Performance scaling suffers
- Manageable for data & request parallel apps
- Very difficult problem for other two:
 - Functional parallelism
 - Automatically extracted

Coordinating Work

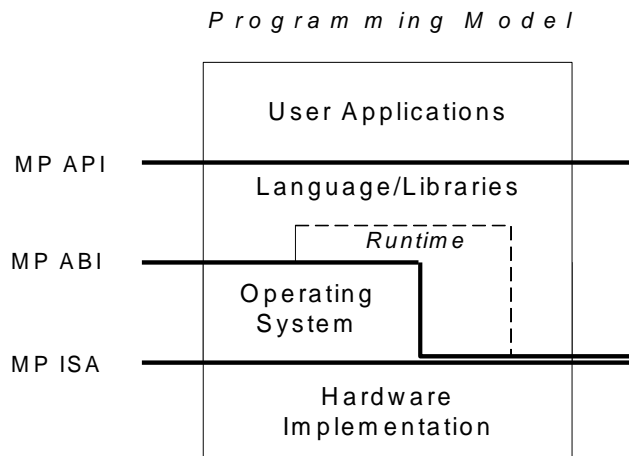

- Synchronization & Communication
 - Some data somewhere is shared
 - Coordinate/order updates and reads
 - Otherwise \rightarrow chaos
- Traditionally: locks and mutual exclusion
 - Hard to get right, even harder to tune for performance
- Research into practice: Transactional Memory
 - Programmer: Declare potential conflict
 - Hardware and/or software: speculate & check
 - Commit or roll back and retry

Expressing Parallelism

- SIMD – Cray-1 case study (later)
 - MMX, SSE/SSE2/SSE3/SSE4, AVX at small scale
- SPMD – GPGPU model (later)
 - All processors execute same program on disjoint data
 - Loose synchronization vs. rigid lockstep of SIMD
- MIMD – most general (this lecture)
 - Each processor executes its own program
- Expressed through standard interfaces
 - API, ABI, ISA

MP (Multiprocessor) Interfaces

- *Levels of abstraction* enable complex system designs (such as MP computers)
- Fairly natural extensions of uniprocessor model
 - Historical evolution

B. Programming Models

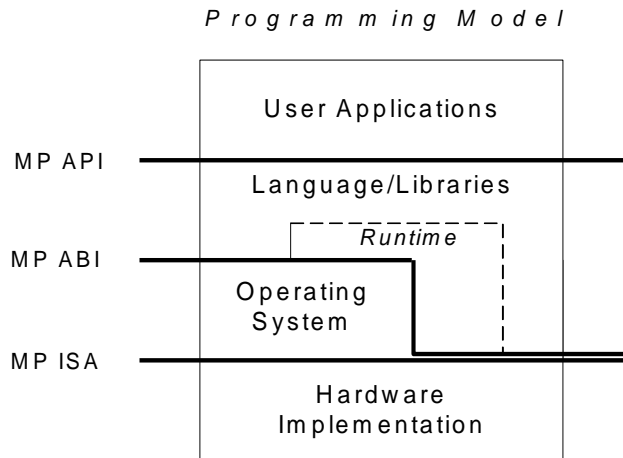

- High level paradigms for expressing an algorithm
 - Examples:
 - Functional
 - Sequential, procedural
 - Shared memory
 - Message Passing
- Embodied in high level languages that support concurrent execution
 - Incorporated into HLL constructs
 - Incorporated as libraries added to existing sequential language
- Top level features:
 - For conventional models – shared memory, message passing
 - Multiple threads are conceptually visible to programmer
 - Communication/synchronization are visible to programmer

Application Programming Interface (API)

- Interface where HLL programmer works
- High level language plus libraries
 - Individual libraries are sometimes referred to as an “API”
- User level runtime software is often part of API implementation
 - Executes procedures
 - Manages user-level state
- Examples:
 - C and pthreads
 - FORTRAN and MPI

Application Binary Interface (ABI)

- Program in API is compiled to ABI
- Consists of:
 - OS call interface
 - User level instructions (part of ISA)

Instruction Set Architecture (ISA)

- Interface between hardware and software
 - What the hardware implements
- Architected state
 - Registers
 - Memory architecture
- All instructions
 - May include parallel (SIMD) operations
 - Both non-privileged and privileged
- Exceptions (traps, interrupts)

C. Major Abstractions

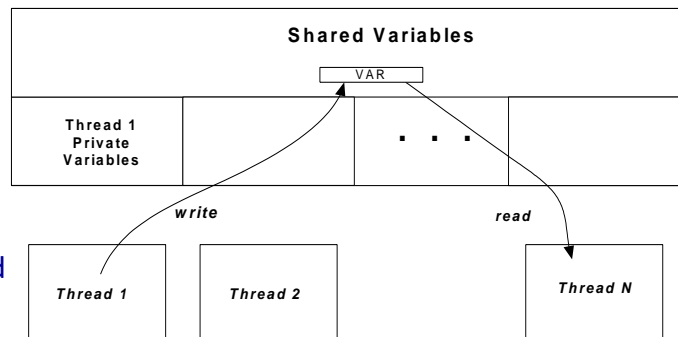

- For both Shared Memory & Message Passing (programming models)
- Processes and Threads (parallelism expressed)
 - **Process:** A shared address space and one or more threads of control
 - **Thread:** A program sequencer and private address space
 - **Task:** Less formal term – part of an overall job
 - Created, terminated, scheduled, etc.
- Communication (coordination)
 - Passing of data
- Synchronization (coordination)
 - Communicating control information
 - To ensure reliable, deterministic communication

D. Shared Memory (outline)

- **Shared Memory Model**
 - API-level Processes, Threads
 - API-level Communication
 - API-level Synchronization
- **Shared Memory Implementation**
 - Implementing Processes, Threads at ABI/ISA levels
 - Implementing Communication at ABI/ISA levels
 - Implementing Synchronization at ABI/ISA levels

Shared Memory Model

- Flat shared memory or object heap
 - Synchronization via memory variables enables reliable sharing
- Single process
- Multiple threads per process
 - Private memory per thread
- Typically built on shared memory hardware system

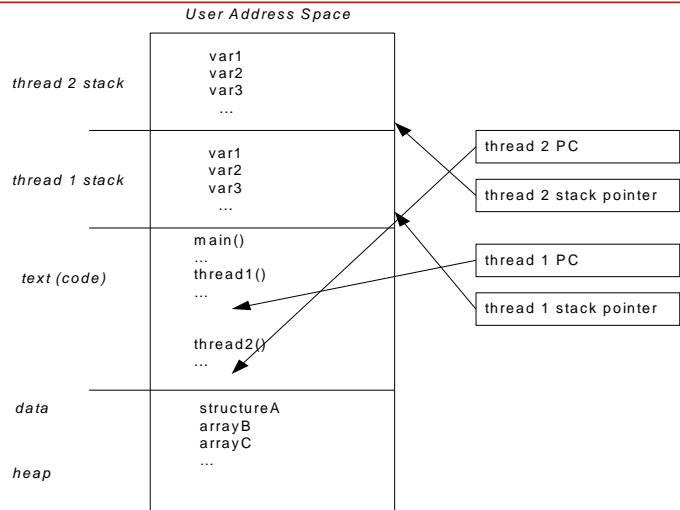

Threads and Processes

- Creation
 - generic -- Fork
 - (Unix forks a process, not a thread)
 - pthread_create(....*thread_function....)
 - creates new thread in current address space
- Termination
 - pthread_exit
 - or terminates when thread_function terminates
 - pthread_kill
 - one thread can kill another

Example

- Unix process with two threads
(PC and stack pointer actually part of ABI/ISA implementation)

10/28/2014 (© J.P. Shen)

Lecture 15

Carnegie Mellon University 21

Shared Memory Communication

- Reads and writes to shared variables via normal language (assignment) statements (e.g. assembly load/store)

Thread 0	Thread 1	Thread 0	Thread 1
	load r1, A addi r1, r1, 3	load r1, A addi r1, r1, 1 store r1, A	
load r1, A addi r1, r1, 1 store r1, A	store r1, A		load r1, A addi r1, r1, 3 store r1, A
	(a)		(b)
Thread 0	Thread 1	Thread 0	Thread 1
	load r1, A addi r1, r1, 3 store r1, A	load r1, A addi r1, r1, 1	
load r1, A addi r1, r1, 1 store r1, A			load r1, A addi r1, r1, 3 store r1, A
	(c)	store r1, A	(d)

10/28/2014 (© J.P. Shen)

Lecture 15

Carnegie Mellon University 22

Shared Memory Synchronization

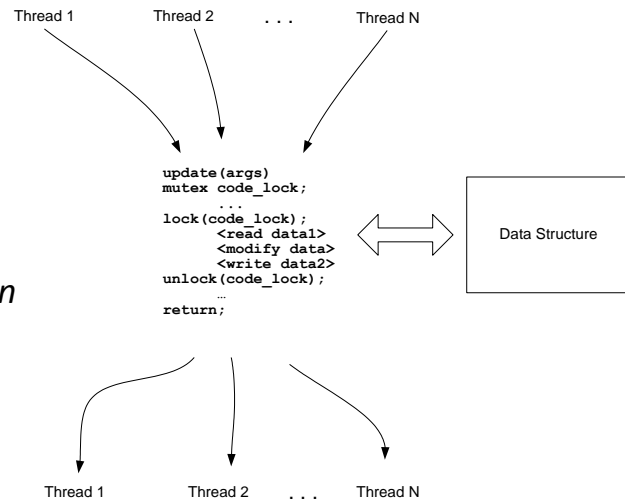

- What really gives shared memory programming its structure
- Usually explicit in shared memory model
 - Through language constructs or API
- Three major classes of synchronization
 - Mutual exclusion (mutex)
 - Point-to-point synchronization
 - Rendezvous
- Employed by *application design patterns*
 - *A general description or template for the solution to a commonly recurring software design problem.*

Mutual Exclusion (mutex)

- Assures that only one thread at a time can access a code or data region
- Usually done via *locks*
 - One thread acquires the lock
 - All other threads excluded until lock is released
- Examples
 - `pthread_mutex_lock`
 - `pthread_mutex_unlock`
- Two main application programming patterns
 - Code locking
 - Data locking

Code Locking

- Protect shared data by locking the code that accesses it
- Also called a *monitor* pattern
- Example of a *critical section*

10/28/2014 (© J.P. Shen)

Lecture 15

Carnegie Mellon University 25

Data Locking

- Protect shared data by locking data structure

10/28/2014 (© J.P. Shen)

Lecture 15

Carnegie Mellon University 26

Data Locking

- Preferred when data structures are read/written in combinations
- Example:

<thread 0>	<thread 1>	<thread 2>
Lock (mutex_struct1)	Lock (mutex_struct1)	Lock (mutex_struct2)
Lock (mutex_struct2)	Lock (mutex_struct3)	Lock (mutex_struct3)
<access struct1>	<access struct1>	<access struct2>
<access struct2>	<access struct3>	<access struct3>
Unlock (mutex_data1)	Unlock (mutex_data1)	Unlock (mutex_data2)
Unlock (mutex_data2)	Unlock (mutex_data3)	Unlock (mutex_data3)

Deadlock

- Data locking is prone to deadlock
 - If locks are acquired in an unsafe order
- Example:

<thread 0>	<thread 1>
Lock (mutex_data1)	Lock (mutex_data2)
Lock (mutex_data2)	Lock (mutex_data1)
<access data1>	<access data1>
<access data2>	<access data2>
Unlock (mutex_data1)	Unlock (mutex_data1)
Unlock (mutex_data2)	Unlock (mutex_data2)

- Complexity
 - Disciplined locking order must be maintained, else deadlock
 - Also, composability problems
 - Locking structures in a nest of called procedures

Efficiency

- Lock Contention
 - Causes threads to wait
- Function of lock *granularity*
 - Size of data structure or code that is being locked
- Extreme Case:
 - “One big lock” model for multithreaded OSes
 - Easy to implement, but very inefficient
- Finer granularity
 - + Less contention
 - More locks, more locking code
 - Perhaps more deadlock opportunities
- Coarser granularity
 - Opposite +/- of above

Point-to-Point Synchronization

- One thread signals another that a condition holds
 - Can be done via API routines
 - Can be done via normal load/stores
- Examples
 - `pthread_cond_signal`
 - `pthread_cond_wait`
 - suspends thread if condition not true
- Application program pattern
 - Producer/Consumer

```
<Producer>
while (full == 1){}; wait
buffer = value;
full = 1;
```

```
<Consumer>
while (full == 0){}; wait
b = buffer;
full = 0;
```

Rendezvous

- Two or more cooperating threads must reach a program point before proceeding
- Examples
 - Wait for another thread at a join point before proceeding
 - example: `pthread_join`
 - Barrier synchronization
 - many (or all) threads wait at a given point
- Application program pattern
 - Bulk synchronous programming pattern

Bulk Synchronous Program Pattern

Summary: Synchronization and Patterns

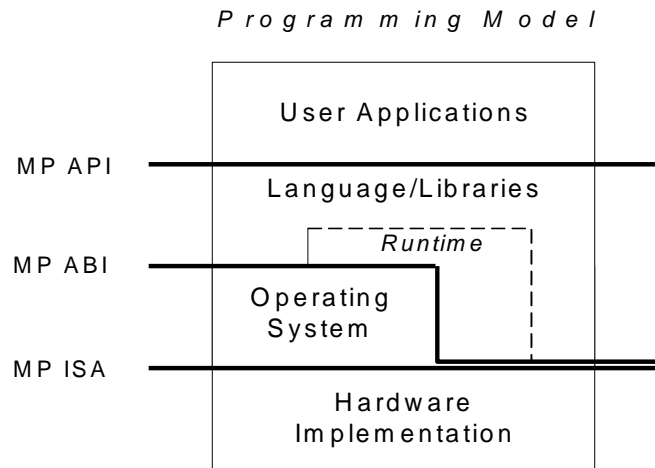

- Mutex (mutual exclusion)
 - Code locking (monitors)
 - Data locking
- Point to point
 - Producer/consumer
- Rendezvous
 - Bulk synchronous

D. Shared Memory (outline)

- Shared Memory Model
 - API-level Processes, Threads
 - API-level Communication
 - API-level Synchronization
- **Shared Memory Implementation**
 - Implementing Processes, Threads at ABI/ISA levels
 - Implementing Communication at ABI/ISA levels
 - Implementing Synchronization at ABI/ISA levels

API Implementation

- Implemented at ABI and ISA level
 - OS calls
 - Runtime software
 - Special instructions

Processes and Threads

- Three models
 - OS processes
 - OS threads
 - User threads

OS Processes

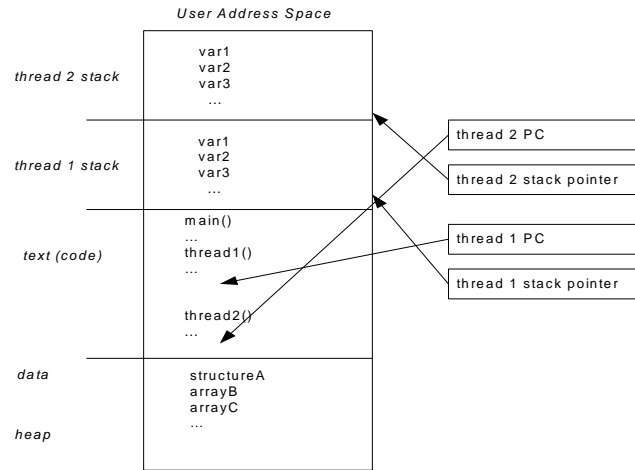

- Thread == Process
- Use OS fork to create processes
- Use OS calls to set up shared address space
- OS manages processes (and threads) via run queue
- Heavyweight thread switches
 - OS call followed by:
 - Switch address mappings
 - Switch process-related tables
 - Full register switch
- Advantage
 - Threads have protected private memory

OS (Kernel) Threads

- API `pthread_create()` maps to Linux `clone()`
 - Allows multiple threads sharing memory address space
- OS manages threads via run queue
- Lighter weight thread switch
 - Still requires OS call
 - OS switches architected register state and stack pointer

User Threads

- If memory mapping doesn't change, why involve OS at all?
- Runtime creates threads simply by allocating stack space
- Runtime switches threads via user level instructions
 - thread switch via jumps

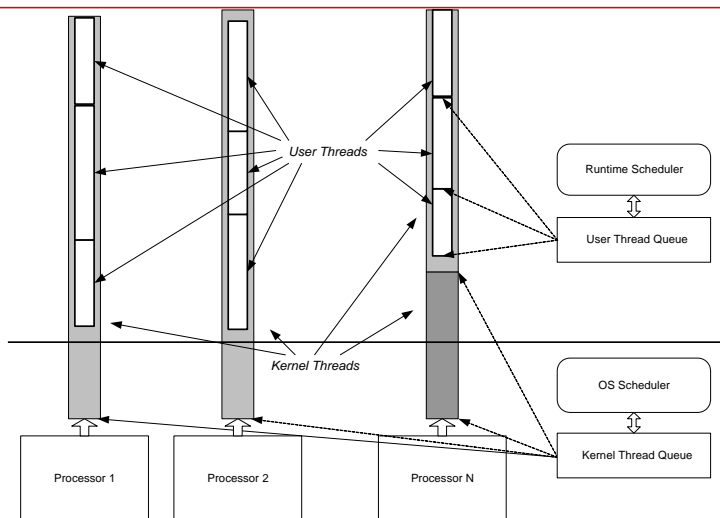

10/28/2014 (© J.P. Shen)

Lecture 15

Carnegie Mellon University 39

Implementing User Threads

- Multiple kernel threads needed to get control of multiple hardware processors
- Create kernel threads (OS schedules)
- Create user threads that runtime schedules onto kernel threads

10/28/2014 (© J.P. Shen)

Lecture 15

Carnegie Mellon University 40

Communication

- *Easy*
Just map high level access to variables to ISA level loads and stores
- *Except for*
Ordering of memory accesses -- later

Synchronization

- Implement locks and rendezvous (barriers)
- Use loads and stores to implement lock:

<code><thread 0></code>	<code><thread 1></code>
<code>.</code>	<code>.</code>
<code>.</code>	<code>.</code>
<code>LAB1: Load R1, Lock</code>	<code>LAB2: Load R1, Lock</code>
<code>Branch LAB1 if R1==1</code>	<code>Branch LAB2 if R1==1</code>
<code>Enter R1, 1</code>	<code>Enter R1, 1</code>
<code>Store Lock, R1</code>	<code>Store Lock, R1</code>
<code>.</code>	<code>.</code>
<code><critical section></code>	<code><critical section></code>
<code>.</code>	<code>.</code>
<code>Enter R1, 0</code>	<code>Enter R1, 0</code>
<code>Store Lock, R1</code>	<code>Store Lock, R1</code>

Lock Implementation

- *Does not work*
- Violates mutual exclusion if both threads attempt to lock at the same time
 - In practice, may work *most* of the time...
 - Leading to an unexplainable system hang every few days

<thread 0>	<thread 1>
<pre> . . LAB1: Load R1, Lock Branch LAB1 if R1==1 Enter R1, 1 Store Lock, R1 </pre>	<pre> . . LAB2: Load R1, Lock Branch LAB2 if R1==1 Enter R1, 1 Store Lock, R1 </pre>

10/28/2014 (© J.P. Shen)

Lecture 15

Carnegie Mellon University 43

Lock Implementation

- Reliable locking can be done with *atomic* read-modify-write instruction
- Example: test&set
 - read lock and write a one
 - some ISAs also set CCs (test)

<thread 1>	<thread 2>
<pre> . LAB1: Test&Set R1, Lock Branch LAB1 if R1==1 . <critical section> . Reset Lock </pre>	<pre> . LAB2: Test&Set R1, Lock Branch LAB2 if R1==1 . <critical section> . Reset Lock </pre>

10/28/2014 (© J.P. Shen)

Lecture 15

Carnegie Mellon University 44

Atomic Read-Modify-Write

- Many such instructions have been used in ISAs

```
Test&Set(reg,lock)
reg ← mem(lock);
mem(lock) ← 1;
```

```
Fetch&Add(reg,value,sum)
reg ← mem(sum);
mem(sum) ← mem(sum)+value;
```

```
Swap(reg,opnd)
temp ← mem(opnd);
mem(opnd) ← reg;
reg ← temp
```

- More-or-less equivalent
 - One can be used to implement the others
 - Implement Fetch&Add with Test&Set:

```
try: Test&Set(lock);
     if lock == 1 go to try;
     reg ← mem(sum);
     mem(sum) ← reg+value;
     reset (lock);
```

Lock Efficiency

- Spin Locks
 - tight loop until lock is acquired

```
LAB1: Test&Set R1, Lock
      Branch LAB1 if R1==1
```

- Inefficiencies:
 - Memory/Interconnect resources, spinning on read/writes
 - With a cache-based systems,
 - writes \Rightarrow lots of coherence traffic
 - Processor resource
 - not executing useful instructions

Efficient Lock Implementations

- Test&Test&Set

- spin on check for unlock only, then try to lock
- with cache systems, all reads can be local
 - no bus or external memory resources used

```
test_it: load      reg, mem(lock)
          branch   test_it if reg==1
lock_it: test&set  reg, mem(lock)
          branch   test_it if reg==1
```

- Test&Set with Backoff

- Insert delay between test&set operations (not too long)
- Each failed attempt \Rightarrow longer delay
(Like ethernet collision avoidance)

Efficient Lock Implementations

- Solutions just given save memory/interconnect resource
 - Still waste processor resource
- Use runtime to suspend waiting process
 - Detect lock
 - Place on wait queue
 - Schedule another thread from run queue
 - When lock is released move from wait queue to run queue

Point-to-Point Synchronization

- Can use normal variables as flags

```
while (full == 1){} ;spin    while (full == 0){} ;spin
a = value;                  b = value;
full = 1;                   full = 0;
```

- Assumes sequential consistency (later)
 - Using normal variables may cause problems with relaxed consistency models
- May be better to use special opcodes for flag set/clear

Barrier Synchronization

- Uses a lock, a counter, and a flag
 - lock for updating counter
 - flag indicates all threads have incremented counter

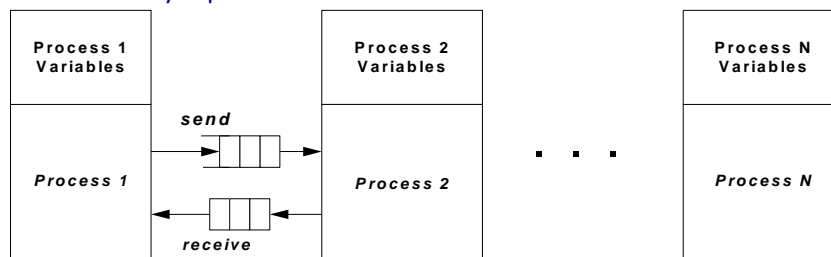

```
Barrier (bar_name, n) {
    Lock (bar_name.lock);
    if (bar_name.counter == 0) bar_name.flag = 0;
    mycount = bar_name.counter++;
    Unlock (bar_name.lock);
    if (mycount == n) {
        bar_name.counter = 0;
        bar_name.flag = 1;
    }
    else while(bar_name.flag == 0) {}; /* busy wait */
}
```

E. Message Passing (outline)

- Message Passing Model
 - API-level Processes, Threads
 - API-level Communication
 - API-level Synchronization
- Message Passing Implementation
 - Implementing Processes, Threads at ABI/ISA levels
 - Implementing Communication at ABI/ISA levels
 - Implementing Synchronization at ABI/ISA levels

Message Passing

- Multiple processes (or threads)
- Logical data partitioning
 - No shared variables
- Message Passing
 - Threads of control communicate by sending and receiving messages
 - May be implicit in language constructs
 - More commonly explicit via API

MPI – Message Passing Interface API

- A widely used standard
 - For a variety of distributed memory systems
 - SMP Clusters, workstation clusters, MPPs, heterogeneous systems
- Also works on Shared Memory MPs
 - Easy to emulate distributed memory on shared memory HW
- Can be used with a number of high level languages

Processes and Threads

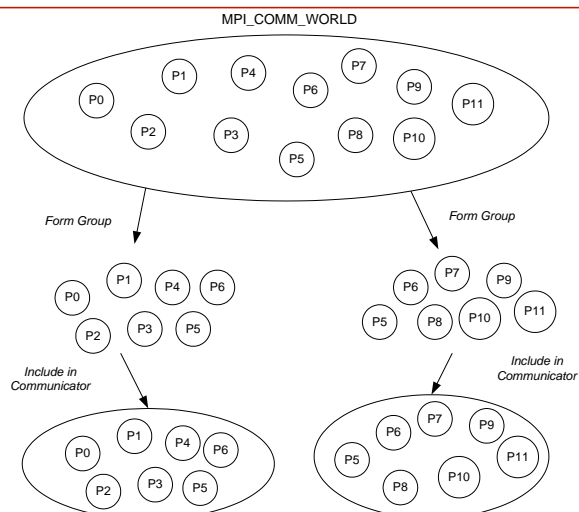

- Lots of flexibility (advantage of message passing)
 - 1) Multiple threads sharing an address space
 - 2) Multiple processes sharing an address space
 - 3) Multiple processes with different address spaces and different OSes
- 1) and 2) are easily implemented on shared memory hardware (with single OS)
 - Process and thread creation/management similar to shared memory
- 3) probably more common in practice
 - Process creation often external to execution environment; e.g. shell script
 - Hard for user process on one system to create process on another OS

Process Management

- Processes are given identifiers (PIDs)
 - “rank” in MPI
- Process can acquire own PID
- Operations can be conditional on PID
- Message can be sent/received via PIDs

Process Management

- Organize into groups
 - For collective management and communication

Communication and Synchronization

- Combined in the message passing paradigm
 - Synchronization of messages part of communication semantics
- Point-to-point communication
 - From one process to another
- Collective communication
 - Involves groups of processes
 - e.g., broadcast

Point to Point Communication

- Use sends/receives primitives
- Send(RecProc, SendBuf,...)
 - RecProc is destination (wildcards may be used)
 - SendBuf names buffer holding message to be sent
- Receive(SendProc, RecBuf,...)
 - SendProc names sending process (wildcards may be used)
 - RecBuf names buffer where message should be placed

MPI Examples

- `MPI_Send(buffer,count,type,dest,tag,comm)`
 - `buffer` – address of data to be sent
 - `count` – number of data items
 - `type` – type of data items
 - `dest` – rank of the receiving process
 - `tag` – arbitrary programmer-defined identifier
 - tag of send and receive must match
 - `comm` – communicator number
- `MPI_Recv(buffer,count,type,source,tag,comm,status)`
 - `buffer` – address of data to be sent
 - `count` – number of data items
 - `type` – type of data items
 - `source` – rank of the sending process; may be a wildcard
 - `tag` – arbitrary programmer-defined identifier; may be a wildcard
 - tag of send and receive must match
 - `comm` – communicator number
 - `status` – indicates source, tag, and number of bytes transferred

Message Synchronization

- After a send or receive is executed...
 - *Has message actually been sent? or received?*
- Asynchronous versus Synchronous
 - Higher level concept
- Blocking versus non-Blocking
 - Lower level – depends on buffer implementation
 - *but is reflected up into the API*

Synchronous vs. Asynchronous

- Synchronous Send
 - Stall until message has actually been received
 - Implies a message acknowledgement from receiver to sender
- Synchronous Receive
 - Stall until message has actually been received
- Asynchronous Send and Receive
 - Sender and receiver can proceed regardless
 - Returns *request handle* that can be tested for message receipt
 - Request handle can be tested to see if message has been sent/received

Blocking vs. Non-Blocking

- *Blocking send* blocks if send buffer is not available for new message
- *Blocking receive* blocks if no message in its receive buffer
- Non-blocking versions don't block...
- Operation depends on buffering in implementation

Blocking vs. Non-Blocking

- Buffer implementations

a) Message goes directly from sender to receiver
reduces copying time

b) Message is buffered by system in between
may free up send buffer sooner (less blocking)

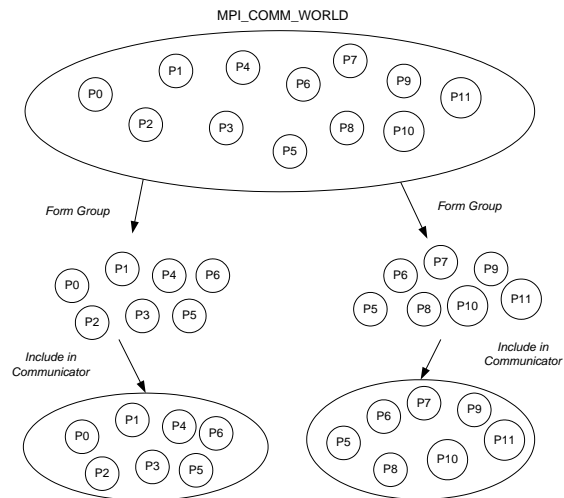

Collective Communications

- Involve all processes within a communicator
- Blocking
- MPI_Barrier (comm)
 - Barrier synchronization
- MPI_Bcast (*buffer, count, datatype, root, comm)
 - Broadcasts from process of rank "root" to all other processes
- MPI_Scatter (*sendbuf, sendcnt, sendtype, *recvbuf, recvcnt, recvtype, root, comm)
 - Sends different messages to each process in a group
- MPI_Gather (*sendbuf, sendcnt, sendtype, *recvbuf, recvcount, recvtype, root, comm)
 - Gathers different messages from each process in a group
- Also reductions

Communicators and Groups

- Define collections of processes that may communicate
 - Often specified in message argument
 - `MPI_COMM_WORLD` – predefined communicator that contains all processes

Message Passing Implementation

- At the ABI and ISA level
 - No special support (beyond that needed for shared memory)
 - Most of the implementation is in the runtime
 - user-level libraries
 - Makes message passing relatively portable
- Three implementation models (given earlier)
 - 1) Multiple threads sharing an address space
 - 2) Multiple processes sharing an address space
 - 3) Multiple processes with non-shared address space (and different Oses)

Multiple Threads Sharing Address Space

- Runtime manages buffering and tracks communication
 - Communication via normal loads and stores using shared memory
- Example: Send/Receive
 - Send calls runtime, runtime posts availability of message in runtime-managed table
 - Receive calls runtime, runtime checks table, finds message
 - Runtime copies data from send buffer to store buffer via load/stores
- Fast/Efficient Implementation
 - May even be advantageous over shared memory paradigm
 - considering portability, software engineering aspects
 - Can use runtime thread scheduling
 - Problem with protecting private memories and runtime data area

Multiple Processes Sharing Address Space

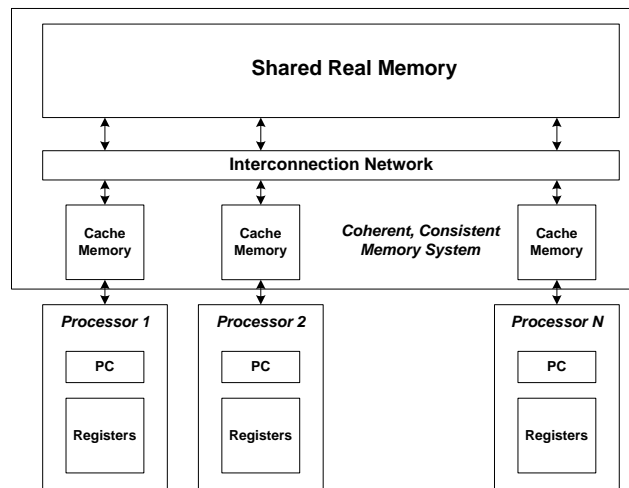

- Similar to multiple threads sharing address space
- Would rely on kernel scheduling
- May offer more memory protection
 - With intermediate runtime buffering
 - User processes can not access others' private memory

Multiple Processes with Non-Shared Address Space

- Most common implementation
- Communicate via networking hardware
- Send/receive to runtime
 - Runtime converts to OS (network) calls
- Relatively high overhead
 - Most HPC systems use special low-latency, high-bandwidth networks
 - Buffering in receiver's runtime space may save some overhead for receive (doesn't require OS call)

At the ISA Level: Shared Memory

- Multiple processors
- Architected shared virtual memory
- Architected Synchronization instructions
- Architected Cache Coherence
- Architected Memory Consistency

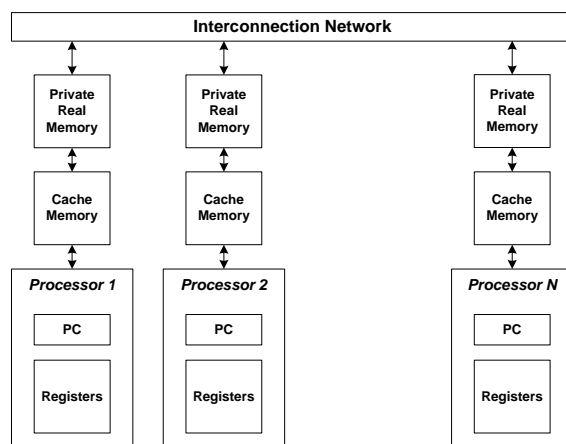

10/28/2014 (© J.P. Shen)

Lecture 15

Carnegie Mellon University 73

At the ISA Level: Message Passing

- Multiple processors
- Shared or non-shared real memory (multi-computers)
- Limited ISA support (if any)
 - An advantage of distributed memory systems --Just connect a bunch of small computers
 - Some implementations may use shared memory managed by runtime

10/28/2014 (© J.P. Shen)

Lecture 15

Carnegie Mellon University 74
